cluster analysis of relative abundance of species 171
coralline species from W. Pyrenean Basin 166, 168, 170
coralline red algae (Oligocene–Miocene), (Cont’d)
New Zealand, coralline genera from algal limestones 170–1
primarily reported from C. and S. Europe 166, 168, 169
recently new taxonomical concepts applied 169
reported in a wide range of depositional settings 172, 174
taxonomic descriptions/reports scarce in E. Tethys 169–70
W. India, non-geniculate and geniculate corallines 169
possible existence of temperate phytogeographic region 175–6
present-day seas, rhodoliths with living algal covers 165–6
reported over large latitude interval 166, 166, 167–8
Sarmatian corallines 174, 175
sub-tropical Mediterranean region delimited 175
tropical phytogeographical region defined 175
validity of many fossil species names questionable 166, 169
dacite ignimbrites 130
Daito Formation 249
Deep Sea Drilling Project 1, 4–5
deep sea temperatures inferred from foraminiferal Mg/Ca ratios 1–14
age models 5–6
recent obitally tuned age for some of mid-Miocene 5–6
Site 1171 Mg/Ca record 5
analytical limitations 11–12
changes in seawater geochemistry 10–11
data compilation, site 747 2, 4, 4
*Cibicidoides* calibration may be used 4
revision of age model 6
data compilation, Sites 926 and 806 2, 4, 5
Site 806, record consistent with Gradstein 6
Site 926, an orbitally tuned age 5
data compilation, Site 1088 2, 4, 5
age model revised 6
located on the Agulhas Ridge 5
Mg/Ca data generated at intermediate water 5
data compilation, Site 1171 2, 4, 5
located within Antarctic Circumpolar Current 5
data compilation, Site 1218 2, 4, 4
Mg/Ca cleaning procedure 4
record has orbitally tuned age 5
site just above calcium carbonate compensation depth 4
Late Miocene 8–9, 10
Mg/Ca data, Site 1088 agrees with Site 926 9
Mg/Ca derived palaeotemperature records provide a spatial view 9
Site 926 and Site 806 8–9
Site 1088, foraminal values relatively constant 8, 10
Mg/Ca derived palaeotemperature records provide spatial view 11
Mg/Ca palaeothermometry 2–4
constraining changes in seawater Mg/Ca ratios through time 3–4, 3
Middle Miocene 7
during ice growth surface waters cooled stepwise 7, 9
ocean circulation changes and mid-Miocene cooling 7
Site 1171, palaeotemperature record 7, 9
neogene overview 6–7
δ18O record 6–7, 6
Mg-derived palaeotemperatures 6, 7
return to warmer temperatures, end of Middle Miocene 7
Oligocene/Miocene boundary 7, 8
boundary event marked by decrease in Mg/Ca ratios 7, 8
Site 474, δ18O max precedes temperature minimum 6, 7
Site 1218, highly resolved palaeotemperature history 7
palaeotemperatures through time 12–14
alternative view, late Miocene and the warming event 13
beginning of enhanced carbonate preservation in the Atlantic 13
difference between Atlantic and Pacific δ13C records, use of 13
late Miocene, formation of cool North Atlantic Deep Water 13
late Oligocene–Miocene, palaeotemperatures higher than modern oceans 12–13, 12
modern ocean temperatures, deep and intermediate water sites 12, 12
North Atlantic Deep Water characterized by high carbonate-ion concentration 13–14
Northern Component Deep Water formation 13
uncertainties in palaeotemperature reconstructions 10–11, 77
*Dendraster excentricus* 208, 209, 211

photozoan carbonates, Neogene basins of SE Spain 54–7
Messinian coral reefs appear at three levels 52, 55
Bioherm Unit 55, 56
Fringing Reef Unit 55
reef core, coral-stromatolite framework 55, 56
Tortonian reefs 218
occur as patch reefs in delta complexes 55
related to fan deltas 55, 55
zoanthellate coral reefs present 52, 54–5, 54

Phymatolithon 155, 155, 159, 160, 174

Planorbulina 96
platform architecture, determined mainly by ecological accommodation 89–90
platform carbonates in Mediterranean-linked basins 51–7
facies and sedimentary models 52–7
platform carbonates in Mediterranean-linked basins (Cont’d)
photozoan carbonates 54–7
shallow-water heterozoan carbonates 52–4
heterozoan and photozoan units 51
alternate in infill of the basins 51
coral-reef development 51, 52
rapid decline in coral diversity, Late Miocene, in Betic basins 56

Platygyra 55
Plicatiforma latisulca 184
Porites 55, 75, 81, 93, 130, 261, 265, 275, 276
Porosononion granosum 186
Posidonian shales 212
Psammechinus philanthropus 219
Punta Trempu section: carbonate platform development at top of isolated fault block 269–73
algal assemblages dominated by Melobesioideae and Mastophoroideae 272
bryozoan-dominated deposits occur in deeper parts of the shelf 272
carbonate succession, vertically stacked, redenned and heavily bored surfaces 269
complex internal geometries often formed 271, 272
coralline red algae dominate skeletal debris 269
evidence for early cementation processes widespread 272
foramol limestones logged 268, 269, 270
interpretation 272–3
carbonate lithofacies with coarse rudstones and floatstones 272
ENE incisions built up an efficient sediment drainage system 271, 272–3
exported sediments deposited in marginal high-energy settings 271, 272
sediments periodically removed from productive areas 272
temperate-type carbonate factory in the Aquitanian 272
rapid facies transitions and complex strata geometries towards the E. 269, 271
scours and channels recognized in the marginal area 269, 271, 271
algal assemblages 272
channel-fill, coarse gravelly deposits 272
channels commonly associated with mound-shaped units 271, 272
channels deeply eroded into previous deposits 271, 271
rhodoliths spheroidal or sub-spheroidal 272
syn-rift breccias, rich in shallow-marine skeletal remains 269
local ostreid banks 268, 269
mixed deposits grade upsection into pure bioclastic limestone 269

Ragusa Formation 73, 73
Ragusa Island, echinoid content high in samples from 218
Ragusa Platform, facies models and geometries of 71–85
changes in ecological parameters, potential factors 83, 85
carbonate mineralogy, possible controls on 83, 85
change of carbonate production across the Ser4/Tor1 sequence boundary 83
chemical properties of seawater, a limiting factor in carbonate production 83
high salinity values, limiting factor for chlorozoan and chloralgal associations 83
facies-zone models and platform geometry 76–81
Ragusa Ramp during the early Tortonian 80–1
Ragusa Ramp during the Late Serravallian 76–80
two modes of carbonate production 76
geological setting 72–3
deposition at front of NW Sicilian-Maghrebian foreland 73
location 72–3, 72
slow and homogenous tectonic subsidence before uplift 73
internal architecture/depositional profile evolution 83
basinward extension of euphotic carbonate production 82, 83
carbonate production at Serravallian/Tortonian boundary 83
low-angle, distally steepened ramp geometry 83, 84
major change in carbonate production 81
middle ramp (chlorozoan-rhodalgal assemblage) 81
minor changes in carbonate production, profound consequences for platform geometry 85
processes of carbonate production and distribution 81–3
accumulation of rhodalgal sediments 82
carbonate production, early Tortonian 82–3, 82
foramol sediments, Late Serravallian 81–2, 82
internal architecture and depositional profile evolution 83
patch reefs of encrusting Vermetidae 83
potential factors responsible for changes in ecological parameters 83–5
sediment nomenclature 74
deposition of rhodalgal and foramol assemblages 74
“heterozoan” and “photozoan” associations defined 74
terminologies adopted 74, 75
sequence correlation and depositional profile definition 76
and sea-level fall at Serravallian/Tortonian boundary 76
stratigraphic analysis 75–6
data used to reconstruct facies models 72, 75
sequence stratigraphic interpretation 76
three sectors defined along the ramp 76
stratigraphic framework 73–4, 73
two palaeogeographic
domains 72, 73
trophic resource and temperature
influence 74
water-depth estimation 74–5
cannot rely on shallow-water
indicators 74–5
estimates of water depth in
present study 75
Ragusa Platform study, two
different facies models ix, 72
Ragusa Ramp during the early
Tortonian 80–1
inner ramp (chlorozoan
assemblage) 80–1
in-situ Vermetidae constrain
water depth 81
muddy sediments reflect low-
energy euphotic
conditions 81
sediments poorly
represented 80
vertical transition related to
third-order sea-level fall 80
middle ramp (chlorozoan-
rhodalgal assemblage) 81
basinward transition to
rhodalgal floatstones
79, 81
deeper outer algal
pavement 81
inner algal pavement 81
three facies zones defined
78, 81
outer ramp (molechfor
assemblage) 81
Ragusa Ramp during the Late
Serravallian 76–80
inner ramp (foramol
assemblage) 76–7
outer shallow-water
zone 76–7
sediments poorly
represented 76
two facies zones
recognized 76, 77, 85
middle ramp (rhodalgal
assemblage) 77–80
current sweeping of inner algal
pavement 80
deposition of inner and outer
algal pavement 80
inner algal pavement, metre-
scale buildups 77
outer algal pavements 78, 79
red-algal accumulations,
protective armoured
pavement 80
red-algal assemblage changes
basinwards 77–8
sediments easily
recognizable 77
steeper slope marks transition
to outer ramp 78, 80
three facies zones defined
77, 77
outer ramp (molechfor
assemblage) 72, 80
faunal assemblage 79, 80
Palazzolo and Tellaro
formations 80
sediments possibly deposited
in aphotic zone 80
reef development, two contrasting
behaviours
distinguished 32
reefs as climatic tracers 17
rhodalgal association 83, 93, 123,
218
rhodalgal facies 107
in modern settings 102
rhodalgal lithofacies 36, 38, 46, 74
rhodechfor assemblage 38, 219
rhodolith floatstone 153–4
bioerosion 154
bryozoan colonies 153–4
matrix, unsorted bioclastic
sediment 154
size and shape 153, 153
rhodolith rudstone 154, 154
Rifian Corridor(s) 51, 57, 63–4
Riu Corrigas section: slope channel
and related fan 273–4
Channel Complex A 271, 273
Channel Complex B 271, 273
interpretation 273–4
Channel Complex A 270, 271,
273
Channel Complex B, complex
channel-fill
architectures 271, 273
fan complexes correlated to
Channel Complexes A and
B 271, 274
Isili channel, distributary
network in distal
reaches 273–4
Isili channel, mixed erosional
depositional channel 273
Isili Channel fill sequences
extensively exposed 268, 270, 273
channel fill divided into two
complexes 270, 273
S of Is Cungiadiuras area
Fan A and Fan B, separated
by sharp erosion
surface 271, 273
frontal splay complexes 273
internal splay complexes
complex 271, 273
Isili Channel splits into
distributary channels 268, 273
Sa Rocca Manna transect 132,
137–40
bioclastic floatstone bed 138,
138
clinoforams, complex internal
geometries 138, 139
coralline algal debris increase
upsection 137
coralline algal growth 138
interpretation 140
additional high-frequency
sequence forms youngest
deposits 140
bindstone embedded in large-
scale trough cross-bedded
deposits 140
rhodolith cliniform
toplaps 140
upper slopes 138, 139, 140
lower part, packstone and
grainstone beds 137
rhodolith size and shape 138
significant increase in dip of
upper beds 138, 139
topsets of clinoforams, beds have
wavy surfaces 138, 139
zone with inclined bedding
138
Sardinia, central and south
bed-to-bed analyses performed on
individual areas 258, 259
exposures offer good window of
observation 258
Sardinia Rift System, good
examples of carbonate
factories 258
Sardinia rift-basin, factors
influencing carbonate
sedimentation on fault
blocks 277–80
Sardinia rift-basin, factors influencing carbonate sedimentation on fault blocks (Cont’d)
climate vs. ecological controls 280
no evidence for ecological reefs found 280
spread of foramol assemblages 280
collected data shows controls on rift basin carbonate production 277–8
eustatic sea-level variation 278
Burdigalian times, all investigated carbonate factories drowned 278
palaeophysography 278–80
tectonic 278
carbonate rocks thicker on peripheral blocks! 265, 274, 278
largely controls sedimentary patterns in syn-rift basins 278
lithostratigraphic correlation between blocks may be misleading 278
Punta Trempu foramol factory, high production rates 278
very sparse and ambiguous evidence for syn-sedimentary tilting 278
Sarmatimactra eichwaldi 184
Sarmatimactra vitaliana 190
Sarmo the corallines 174, 175
Sarmo the stage 183–4
Sarreoch Fault 260
Schizaster 220
Schizaster parkinsoni/Ditremaster/ Pecten assemblage 220
Scolicia burrows 52
Sedini Limestone (N Sardinia), case study ix
Sedini Limestone Unit 131–2
carbonate platform facies and stratigraphy 144–5, 145
inner ramp 144, 145
latest stage of platform evolution poorly recorded 132, 145
middle to outer ramp deposits 144–5
reef deposits and bindstone 137, 138, 139, 145
sequence 2 deposits 145
two depositional sequences 144, 144
small carbonate platform dissected by NNE–SSE faults 132, 132
stratigraphic architecture 131–2, 132
turnover in geometry 145–6
change of buildup geometry and carbonate factory 146
goes from warm-temperate to tropical 146
up-section change, ramps to reef-rimmed platforms 148
two depositional sequences 131, 132, 144, 144
Sedini transect 142–4
interpretation 143–4
boundary hardground in part of transect 143
facies changes in sequence 1a 143–4
formation of hardground, top of sequence 1a 144
middle ramp environment 144
middle to outer ramp 144
Section 5, bindstone in topmost part 144
reconstructed 132, 142, 142
Section 1 deposits 142–3, 142
Section 4 142, 143
Sections 5–7, limestone strongly bioturbated 143, 143
Sections 6–7
floatstone to rudstone layer 142, 143
limestone coarsens upwards 143
transition, unit and underlying fluvial conglomerate 142
Seioicrinus 212
sequence stratigraphy, “Calcari a Briozi e Litotamni” Formation 121–3
detrital glauconite grains mark LST-TST boundary (DS5) 123
lower sequence 121–2, 123–4, 125
above DS3 Miocene sedimentation extended to East 124
bounding surfaces 119, 121
genometry and stacking pattern of facies belts 119, 124
warm phase peak 124
lower sequence, highstand systems tract (HST) 122
change in carbonate factory 124
developed above DS3 122
NW and SE, accelerated tectonic subsidence 122, 124–5
progressive decrease in thickness towards NW 119, 122
rhodolithic limestones, grading to west 122
shows a primary eustatic control 124
lower sequence, lowstand systems tract (LST) 121
aggradation geometry 121
composed of inner-, middle- and outer ramp facies 121
DS2, represents a transgressive surface 121
“Palaeogene hiatus”, variable duration 121
presence of discontinuous conglomerates 119, 121
lower sequence, transgressive systems tract (TST) 119, 121–2
carbonate body grading SE into the rhodolithic facies 121–2
maximum-flooding surface (glauconitized) 122
rapid spread of bryomol lithofacies, results 122
significant change in the carbonate factory 124
reconstruction of 121 reflects two second-order depositional sequences 119, 121
strongly influenced by tectonics 123
upper sequence 122–3, 124–5
DS4, interpreted as a sequence boundary 122
eastward-younging 122
exposed in almost entire Latium-Abruzzi region 122
geometry strongly influenced by tectonics 125
lower boundary of DS4 sequence 124–5
lower boundary (DS4), W and S sectors 122
significant change in central sector 122
tentatively interpreted in terms of sequence stratigraphy 122
upper sequence, lowstand systems tract (LST) 123
conditioned by tectonic subsidence 123
NE sector, discontinuity surface 113–15, 117, 123
sea-level fall at base of sequence 123
technically-induced termination of 123
upper sequence, transgressive systems tract (TST) 123
deep conditions suggested 113–15, 117, 123
interpretation 123
rests on rhodolith floatstone 123
shallow-water carbonate production, molluscs as major part of 183–98
shelf carbonates composed of heterozoan associations 49
cool-water, today extend to the Arctic shelf 50
temperate, echinoderms one of major groups of skeletal fragments 217
shelf-carbonate component associations, two types 49

Siderastrea 55
Sinis Fault 260
Skalica Formation 185
Sorbas Basin 57, 58
Messinian irregular echinoids 220
Sorbas Member 55
Southern Hemisphere
buildups 21–2
Southern Ispilunca Valley Transect 132, 136–7
above Surface II, thick package of large-scale trough-bedding 138
evidence in SE for a dividing surface 136
cliniforms overlie Surface VI 136–7
coral deposits 137, 137
floatstones and rudstones 136
following unit displays no visible sedimentary structures 136
Surface V 136
interpretation 137
depositional relief above the sequence boundary 137
Surface II divides succession into two sequences 137
mainly depositional geometries shown 136, 136
Spatangus 220
Spatangus glenni 219
Sphaeroidinellopsis 62
Spongites 77, 80, 81, 157, 158, 161, 173, 174, 175
Spongites albanensis 157, 158, 159, 160, 162
Sporolithon 81, 138, 158, 158, 171, 174, 175
Strongylocentrotus pallidus 208
Tarbellastraea 55, 130, 261, 276
tectonic subsidence 73, 123, 252
accelerated 122, 124–5
Latium-Abruzzi platform 90, 92
Tellaro Formation 73, 73
Thalassanoidea burrows 94, 140
Thalassinoides nitzschiodes 39
Thegioastrea 130
thermacor facies 45, 46
transgressive systems tracts 98, 101, 123
tropical foram-rhodalgal carbonate ramp, facies and sequence architecture of 107–25
depositional environment 111–19
depositional environment, inner ramp 116
carbonate production in the euphotic zone 116
conglomerate layers described 116
coral carpets/coral colonies 116
facies represents seagrass meadow environment 116
lithofacies included in this association 113–15, 116, 117
depositional environment, middle ramp 118
bioclastic packstone-grainstones 118
depositional environment, oligophotic zone 118
facies represented by rhodolithic limestones 109, 110, 116, 118
made up from different microfacies 113–15, 117
oyster-pectinid-bearing levels 118
tabular bodies from rhodolithic facies 118
depositional environment, outer ramp 118–19
benthic foraminifera-echinoid limestones 113–15, 117
distal outer-ramp lithofacies limestones 113–15, 116, 118
intermediate outer-ramp zone 116, 118
placed in aphotic zone 119
proximal outer ramp, bryozoan-echinoid limestones 113–15, 116, 117, 118
sub-division of 118
upper lithofacies divides into two subunits 113–15, 118
widely represented throughout the platform 118
geological setting 108, 116
age of Miocene transgression 108
“Calcari a Briozoi e Litotamni” Formation 108
carbonate deposition 108
tropical foramol-rhodalgal carbonate ramp, facies and sequence architecture of (Cont’d)
Latium-Abruzzi platform 108, 109
main lithological lithofacies associations 108
main discontinuity surfaces 119–21, 119
DS1, an undulating irregular surface 119, 119
DS2, sharp superposition of different facies 119–20, 119
marked by sharp facies changes 119
methods 108–11
sequence stratigraphic interpretation 108–11
important facies characteristics 113–15
measured sections across the platform 109, 110, 111
recognized lithofacies associations 111, 116
sample reproducibility estimates 111
samples analyzed for Sr isotope composition 111, 112
strontium-isotope stratigraphy used 109–11
use of petrographic and geochemical criteria 111
sequence stratigraphy 121–3
tropical foramol-rhodalgal carbonate ramp, sensitivity of relative to sea-level change 89–102
geological setting 90
ramp sediments, “Calcari a Briozoi e Litotamni” Formation 92–100
Uintacrinus socialis 215
Upper Bryozoan Limestone 124
Uvigerina peregrina 57
