This section covers the ‘toolkit’ of skills and knowledge that you need at the outset of your paediatric attachment. The first chapter sets the scene, putting the paediatrics you will learn in the wider context of child morbidity and mortality, societal issues, and community and social aspects relevant to child public health and paediatric practice.

The skills of history taking and examination are different when assessing children, and the next two chapters help you learn a systematic yet flexible and child friendly approach.

We hope you won’t have the stress of being first on the scene when a child collapses, but you need to know the basics of what to do, and how this differs from adults. This is covered in Emergency paediatrics, along with the equally important skill of being able to recognize impending collapse before it happens. Remember that children can deteriorate quickly, and if you are in doubt, ask for help!
Children and their health

Chapter map

Children under the age of 16 comprise 20% of the population of the UK and of most industrialized countries, but in many developing countries children represent more than 50% of the population. In all countries, the management of children’s health problems is a high proportion of the medical workload. Many GPs find that 30% of their consultations are for children, particularly pre-school children (under 5 years). (Medical students in the middle of a 2- or 3-month paediatric attachment may wonder why only 5% of their training should be devoted to children!) This chapter sets the scene for your study of paediatrics, starting with an overview of child health globally and in the UK. We then review societal factors relevant to paediatrics, community and social aspects of child health, and finally the child in hospital.

Summary, 15

1.1 Global child health

Children make up about 2 billion of the world’s population. Health inequalities between nations are seen most starkly in childhood indicators, such as under-5 mortality rates (Figure 1.1). Most childhood deaths occur in sub-Saharan Africa and south Asia (Figure 1.2), and malnutrition causes or contributes to at least half of them, along with many other factors (Figure 1.3). There has been a sustained international effort in the last few decades to address inequalities, culminating in the Millennium Development Goals adopted in 2000 by all members of the United Nations. These set measurable targets to be achieved by 2015 in relation to poverty, maternal and child health and combating disease such as HIV and malaria. Progress has been made, but much remains to be done.

Under-5 mortality rate (rate/1000 live births)

The under-5 mortality rate is a useful measure of child health internationally. While similar to the infant mortality rate, it detects trends that the infant mortality rate might miss, because in some countries infants dying in the first few weeks are not recorded.

Figure 1.2 Worldwide under-5 mortality rates in year 2000. Numbers are deaths/1000 liveborn infants. There was a large reduction in under-5 mortality worldwide by about 65% from 1960 to 2000. However, from 1990 to 2000, some countries saw an increase in mortality due to HIV and armed conflicts. Reproduced with permission, courtesy of University of California Atlas of Global Inequality (http://ucatlas.ucsc.edu).
1.2 Child mortality and morbidity in the UK

The causes of death and the patterns of illness in children differ markedly from those in adults. They are influenced by a diversity of factors, which include sex, social class, place of birth and season of the year. The decline in child mortality in the past century has resulted more from preventative (public health) measures than from improved treatment. Today virtually the entire population of the UK has safe food and water, free immunization and easy access to local health care. This is not the case in non-industrialized countries.

In the UK, child mortality is concentrated in the perinatal period (Table 1.1). The only remaining scope for a major reduction in child deaths lies in better obstetric, neonatal and infant care.

1.2.1 Infant mortality

- UK infant mortality continues to fall (currently 4.3 per 1000 live births) (Figure 1.4).
- But half the countries in the European Union have lower rates.
### Table 1.1 UK mortality rates

<table>
<thead>
<tr>
<th>Mortality indices</th>
<th>UK rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stillbirth rate (stillbirths per 1000 total births)</td>
<td>5</td>
</tr>
<tr>
<td>Early neonatal mortality rate (deaths in first 7 days per 1000 live births)</td>
<td>3</td>
</tr>
<tr>
<td>Perinatal mortality rate (stillbirths + first week deaths per 1000 total births)</td>
<td>8</td>
</tr>
<tr>
<td>Infant mortality rate (deaths in first year per 1000 live births)</td>
<td>6</td>
</tr>
<tr>
<td>Under-5 mortality rate (deaths in the first 5 years per 1000 live births)</td>
<td>7</td>
</tr>
</tbody>
</table>

- Several East European countries have infant mortality rates 2–3 times higher.
- Some non-industrialized countries have rates over 150.
- Improvement in UK infant mortality:
  - Mainly due to reduction in neonatal mortality
  - Less improvement in post-neonatal mortality (1 month to 1 year).
- Some deaths result from persistent, serious congenital abnormalities and perinatal problems, others due to accidents or diagnosable disorders, but many are infants who die at home, for whom no cause of death is found at postmortem (Section 15.3).

#### 1.2.2 Child mortality

- The major causes of childhood death are neoplasms and accidents.
- Deaths are concentrated in early life and are higher for boys at all ages, by a factor of 1.3 in the first month of life and by 1.6 for children of school age.
- For a schoolchild, death is more likely to be due to an accident, particularly a road accident with the child as pedestrian or cyclist, than to any disease (Figure 1.5).
- The decline in mortality from infectious diseases has made other serious disorders appear more common. Death from malignancy is now as common as from infection (Figures 1.5 and 1.6).

#### 1.2.3 Childhood morbidity

- The pattern of morbidity in children is very different from that of adults (Figure 1.7):
  - Infections are common, especially of the respiratory, gastrointestinal and urinary tracts, as well as the acute exanthemata (e.g. chickenpox).
  - Degenerative disorders and cerebral vascular accidents are very rare.
  - New forms of chronic disease are becoming relatively more important as formerly fatal childhood disorders become treatable (but not necessarily curable):
    - Children with complex congenital heart disease, malignant disease, cystic fibrosis and renal failure benefit from modern life-saving therapies but may not achieve a cure, and often have to live with the difficulties and side-effects of complicated treatment.

The hallmarks of childhood are growth and development, which influence both the kinds and the patterns of childhood illness. Congenital malformations, genetic disease and the consequences of problems in the perinatal period (e.g. cerebral palsy) are common. You do not need to spend much time looking after children to realize that disturbances of development and behaviour, and anxiety about normal variants, are both prevalent and important to parents.

It has been estimated that a British GP with an average practice would see a new case of pyloric stenosis every 4 years, childhood diabetes every 6 years, Down syndrome every 16 years, Turner syndrome every 60 years and haemophilia or Hirschsprung disease every 600 years! Hospitals may give a very false impression of the pattern of illness in the community at large.

---

Stillbirth: a child born dead after the 24th week of pregnancy
Abortion or miscarriage: a fetus born dead before 24 weeks of gestation
Live birth: Any newborn with signs of life (e.g. heart beat) at birth at any gestation.

Figure 1.4 Infant mortality (0–1 years). By 2010, the infant mortality in England and Wales had fallen to a fraction of the level in 1900 (from 156 per 1000 live births to 4.3 per 1000). Even in the last 30 years it has fallen by over 60%.
Chapter 1: Children and their health

Figure 1.5 Causes of death in childhood. Mortality ages 1–14 in 2003. 

1.3 Children in society

1.3.1 Socioeconomic inequalities

Socioeconomic status is a key determinant of child health. The health and educational progress of a child is directly related to the home and the environment. A child in social class V has a 50% greater chance of being born dead or with a serious physical handicap than one in social class I (see Table 1.2). The disadvantage is there at birth and continues throughout childhood. The social class IV or V child will have more accidents, more physical illnesses, will be smaller and will read less well than the child from social class I or II. At any age a child from social class V is twice as likely to die as one from social class I. In many developed countries, health inequalities have grown wider even as average health levels have improved.

The UK has one of the worst rates of child poverty in the industrialized world. The proportion of children living in poverty grew from 1 in 10 in 1979 to 1 in 3 in 1998. Today, 30% of children in Britain (nearly 4 million) are living in poverty. Since 1999, when the Government pledged to end child poverty, 550 000 children have been lifted out of poverty.
1.3.2 Changes in family structure

Family structure has become more fluid in the UK, reflecting changing societal attitudes to marriage, divorce and cohabitation. Children more often have to make transitions to new family structures. They are helped by: family stability; good relationships between partners; avoiding sustained exposure to conflict; and keeping children’s needs paramount.

Although marriage has declined and 40% of births are now outside marriage, 7 out of 10 families are headed by a married couple. Step-family combinations are increasing. With more single-parent families, and families where both parents work, grandparents play a significant role in childcare (at least weekly for 25% of families); 23% of dependent children live in single-parent families. Although UK teenage pregnancy rates have fallen recently, they are still among the highest across developed countries. Half of all teenage mothers live in the 20% most deprived areas.

Home factors that can adversely affect children’s health and development include:

- Parental discord
- Quarrelling
- Separation and divorce
- Domestic violence
- Parental illness
- Death of a parent
- Chronic disability
- Physical illness
- Mental illness
- Inability to cope with demands of parenting
- Abuse
- Financial hardship.

The complexity and multiplicity of the factors that cause a child to be disadvantaged sometimes makes us feel helpless. However, since adversities compound one another, much may be achieved by modifying even one adverse factor.

Extensive medical and social services exist, particularly for handicapped children, but all too often they are best used by well-informed, middle-class parents, while the parents of the disadvantaged child do not use them sometimes because they do not know about them. All medical and paramedical staff have a duty to recognize children in need or in distress, and to see that they benefit from the help that is available.

</tr>
</tbody>
</table>

### KEY POINTS

All children need:
- Self-esteem (we need to feel wanted)
- At least one good human relationship (we need to trust and feel trusted)
- Firm supervision and clear boundaries (we need rules).

A small change that helps to achieve one of these for a child may make a big difference.

Twenty per cent of the world’s population live in absolute poverty. Nearly half of them are children.

1.3.3 Ethnicity

Most countries have ethnic minority communities with particular needs. The UK continues to become more ethnically diverse. In the UK, 15% of the population (and one-third of newborns) are from ethnic minority groups. There is great regional variation. Consanguinity (marrying a blood relative) is more common in some cultures (e.g. some Muslim communities), increasing the risk of recessively inherited disease. Rickets is more common in some ethnic groups due to diet, pigmented skin and lack of exposure to sunlight. There remain significant health inequalities for many minority groups in Europe.

Find out about your own local situation and be aware of cultural and health differences. These range from what names to use, through to differences in patterns of disease, through travel (e.g. malaria), contact (e.g. tuberculosis) or racial susceptibility (e.g. sickle cell disease). Understanding the importance of racial background, family, cultural and religious beliefs improves paediatric care.
1.3.4 Laws relating to the young

For legal purposes, a child remains a ‘child’ up to the age of 18. However, many laws become operative at other ages. School education is compulsory for children aged 5 and over. Children may not leave education until they are 17.

Children may not be employed until they are 13. Then they may be employed only between the hours of 7 a.m. and 7 p.m., and for a maximum of 2 h on school days.

Children under 10 (under 8 in Scotland) are not considered ‘criminally responsible’ for their misdeeds, and may be dealt with by the juvenile courts. The court can make (1) a care order giving parental rights to the local authority; or (2) a supervision order which may be administered by the social services department or, if the child is over 14, by the probation department. At the age of 15 children can be sent to youth custody. Adult courts deal with those over the age of 17. Although it is legally possible to be sent to prison for a first offence at the age of 17, in practice it is rare before the age of 20.

1.3.5 Ethics and children’s rights

In 1989 the United Nations declared that children worldwide should have special rights due to their immaturity and vulnerability. This Convention on the Rights of the Child sets out what every child needs for ‘a safe, happy and fulfilled childhood’. These include the right to health, family life, and to have his views taken seriously in matters affecting him. Consent and competence are covered later (Section 16.2). Once a child is deemed to be competent, then the doctor has the normal duty of confidentiality, including not disclosing information to a third party (including a parent). Sometimes this has to be overridden because of safeguarding concerns, but this should be explained to the child.

A challenging part of intensive care (whether paediatric or neonatal) is the decision to withdraw life-prolonging treatment. Decisions should be made by the treating team in partnership with the parents, taking time to ensure all relevant information is considered.

### Ethnic composition - England and Wales (2011)

<table>
<thead>
<tr>
<th>Ethnicity</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>White</td>
<td>86%</td>
</tr>
<tr>
<td>Asian/Asian British</td>
<td>7.5%</td>
</tr>
<tr>
<td>Black/Black British</td>
<td>3.3%</td>
</tr>
<tr>
<td>Mixed</td>
<td>2.2%</td>
</tr>
<tr>
<td>Other</td>
<td>1%</td>
</tr>
</tbody>
</table>

### Situations where the withholding or withdrawal of life-prolonging treatment might be considered:

- Brain death: brain stem death despite life prolonging care
- Permanent vegetative state: reliant on others for all care and does not react or relate with the outside world
- ‘No chance’ situation: life-sustaining treatment simply delays death
- ‘No purpose’ situation: treatment may save life, but physical or mental impairment is too much to bear
- ‘Unbearable’ situation: further treatment is more than can be borne.

1.4 Child health in the community

1.4.1 Health personnel

1.4.1.1 Community paediatricians

Most paediatricians have a commitment to some services outside of the hospital. Community paediatricians specialize in working outside of the hospital. They work closely with health visitors and the staff of child health clinics, and also with GPs, social and educational services. The boundary between hospital general paediatrics and community paediatrics is increasingly blurred. Community paediatricians often specialize in one or more of the following:

- Child health surveillance
- Provision of children’s services to a specific geographical sector
- Learning problems and disability
- Child protection (child abuse)
- Audiology
- Adoption and fostering
- School health.

1.4.1.2 Health visitors

These are registered nurses with additional training in health promotion and prevention of illness in all age groups. Many are attached to general practices and a few specialize (e.g. in diabetes) and have hospital attachments. They are responsible for family health, and particularly for mothers and pre-school children. Their job is to prevent illness and handicap by giving appropriate advice, by detecting problems early and by mobilizing services to deal with those problems. They have a key role in child health promotion.
1.4.1.3 School nurses

School nurses provide a variety of school-based services:

- Confidential health advice for children and young people
- Sex education
- Developmental screening
- Health interviews
- Immunization programmes
- Working with schools to create a health-promoting environment
- Enuresis management.

1.4.2 Health surveillance and promotion

1.4.2.1 Child health promotion

Child health promotion

- Primary and secondary prevention of problems.

Child health surveillance

- Part of child health promotion
- Secondary prevention through early detection of existing problems.

The core child health promotion programme in the UK includes (Table 1.3):

- Childhood surveillance
- Immunizations
- A systematic process to assess the individual child’s and family’s needs
- Early interventions to address those needs
- Health promotion.

The aim is a flexible, targeted approach in partnership with parents, to ensure that all children’s health and developmental needs are addressed. The programme is a combined undertaking, starting at birth with the postnatal check by the paediatrician or midwife, and then involving the primary health care team: health visitor, GP and later school nurses.

1.4.2.2 Child health clinics

These clinics aim to be readily accessible to young families. They are often in GP surgeries, but may also be located in health centres, village halls or purpose-built accommodation. They are staffed by health visitors and GPs. About 90% of babies attend such a clinic during their first year, but thereafter attendance falls off.

Functions

- Child health surveillance
- Routine medical and developmental examinations for infants and pre-school children
- Immunization
- Health education
- Advice and support for those with special problems.

1.4.2.3 Parent-held child health record

Parents should be encouraged to take the ‘red book’ whenever the child attends clinic or hospital. It contains a permanent record of child health surveillance, the child’s growth including a centile chart, hospital visits, health education and advice (Figure 1.8).

1.4.2.4 Health education and preparation for parenthood

During the final years at school and in the antenatal period, there are numerous opportunities for health education and training in parentcraft. Effective and timely health promotion reduces fetal, infant and childhood morbidity and mortality.

Key messages for parents

- Regular antenatal care
- Avoid smoking and alcohol during pregnancy
- Breast feeding, and information on how to breast- or bottle-feed
- Reduce risk of SIDS (Chapter 15)
- Immunization
- The parent-held record (the red book)
- Good childhood nutrition
- Love, care, nurture and play
- Avoid parental smoking (respiratory disease in children)
- What action to take when your child is ill
- Reduce risks of accidents at home and on the road
- Good dental health.
## Table 1.3 UK Child Health Promotion Programme

<td>- Health or developmental problems to be referred early to specialist team&lt;br&gt;  - For children at risk of obesity&lt;br&gt;  - Advice on healthy eating, portion size and mealtime routines&lt;br&gt;  - Smoking cessation support</td>
</tr>
</tbody>
</table>
Chapter 1: Children and their health

1.4.2.5 Immunization

Immunization is a key part of the programme (Chapter 14).

1.4.3 Schools and nurseries

1.4.3.1 Pre-school facilities

In the UK, all 3- and 4-year-olds are entitled to free part-time early education, which can be in school nurseries, day nurseries, playgroups or with approved childminders.

Nurseries or playgroups may be stand-alone or attached to primary schools. They aim to encourage a child’s development and learning by play, stimulation and physical activity. Infants and younger children may attend day nurseries while their parents are at work, or parent–toddler groups with a parent. Pre-school facilities are particularly important for children from disadvantaged backgrounds. ‘Surestart programmes’ develop facilities for these children, and provide support for parents with young children.
1.4.3.2 Healthy schools

Children spend a large amount of time in school, and the school environment affects their health. The ‘Healthy Schools’ initiative programme in the UK encourages schools to take positive steps towards promoting children’s health.

The social services department of the local authority is responsible for the care and/or supervision of children up to 18 years if:

- Parents are unable to care for their children
  - e.g. illness, abuse
- No parent or carer for children
  - e.g. death of parent(s), child abandoned or lost.

In these situations, the local authority assumes parental rights in order to provide security and protection for the child.

Promotion of regular water-drinking and easy access to clean and well-maintained toilets reduces problems of constipation, urine infections and wetting.

1.5 Social aspects of child health and care

1.5.1 Parental responsibility

Both parents have legal ‘parental responsibility’ if they are married at the time of the child’s birth, or if both are registered on the birth certificate. Otherwise, the mother has parental responsibility, but there are legal mechanisms by which the father can acquire it.

1.5.2 Social services

The social services department of the local authority is responsible for the care and/or supervision of children up to 18 years if:

- Parents are unable to care for their children
  - e.g. illness, abuse
- No parent or carer for children
  - e.g. death of parent(s), child abandoned or lost.

In these situations, the local authority assumes parental rights in order to provide security and protection for the child.

Parental rights may be given to the local authority by the court (usually a family court or juvenile court), in which case a child is said to be the subject of a care order. The court must be satisfied that the child has suffered, or is likely to suffer, significant harm because of the standard of parental care or because of being beyond parental control. ‘Harm’ includes ill-treatment, sexual abuse, and the impairment of good physical and mental health and development.

The local authority tries to keep or place children with their own parents, relatives or friends. When this is not possible, the child is looked after by the local authority in:

- Foster homes (75%) in which a child is cared for in a family other than his own. There are an increasing number of schemes in which the foster parents are paid extra to look after children with physical and mental handicap or disturbed adolescents.
- Residential placements: Children’s homes, residential schools and secure units (25%) aim to provide as normal an upbringing as possible, despite frequent changes of staff. They contain a higher proportion of difficult or handicapped children than foster homes. Of children in these homes, 95% still have a living parent, so that many are visited regularly or may be reunited with their parents for weekends or longer periods.

Children may be supervised in their own homes, either on a voluntary basis or as a result of a court supervision order. The social worker’s prime aim is to prevent family break-up and to help with problems of care, both physical and emotional. He or she works as part of a team with others involved with the family, e.g. health visitors, doctors and teachers.

The social services department is responsible for supervising children placed privately with foster parents. People who look after other people’s children, whether on a day (child day-care, childminder) or residential (foster) basis, must register with their local social services department, even if they are paid

---

**Incidence of some important problems**

**At 5 years:**
- 7% have had at least one seizure
- 5% have a squint
- 5% have a behavioural problem
- 5% have a speech or language problem
- 2% have a substantial congenital defect.

**At 7 years:**
- 15% have eczema, asthma or hay fever
- 13% require special education
- 10% wet their beds
- 2% have had a hernia repair
- <1% have had an appendicectomy.

**Promotion of regular water-drinking and easy access to clean and well-maintained toilets reduces problems of constipation, urine infections and wetting.**

**Disability Living Allowance (DLA)**

- Care allowance from birth for levels of care in excess of those needed by healthy child
- Mobility allowance is available from the age of 5 years.
directly by the parent. Social services also provide advice about financial benefits available from the Department of Social Security.

### 1.5.4 Adoption

Couples wishing to adopt a child approach their local authority who will assess suitability. The process includes medical assessment of the child and parents. Once adopted, the child is a full member of the family; he or she takes their name and has all the rights of a natural child. It is best for parents to inform their child from the beginning that they are adopted.

### 1.6 Children in hospital

Health care for children has changed dramatically in the last 60 years. Children were separated from their parents for long periods with little appreciation of their particular needs. The birth and development of paediatrics as a medical specialty was largely attributable to the first children’s hospitals. Now the special needs of children are recognized in the design and provision of services, e.g. unrestricted visiting, facilities for resident parents, play activities for younger children (Figure 1.9) and education for older children. Every effort is made to minimize a child’s need to stay in hospital. Infants account for more than half of all paediatric admissions (Figure 1.10). The majority of admissions are due to respiratory conditions and infections (Figure 1.11).

Hospitals are not without risk to patients, especially child patients. The hazard of cross-infection is obvious: the hazard of mother–child separation is less obvious but can be more serious, especially among the 1–4-year-olds. At this age, children are old enough to grieve for a lost mother, but not old enough to understand the reason, or that the separation is temporary. ‘Tomorrow’ has no meaning for a toddler.
Chapter 1: Children and their health

Figure 1.10 Number of paediatric in-patient admissions by age. Number of admissions per year in 1000s in the UK of children 0–18 years old. Source: Audit Commission 1993.

Figure 1.11 Causes of paediatric admissions. Based on a study of admissions to a District General Hospital. Respiratory problems (asthma, URTI, bronchiolitis, pneumonia and breathing difficulties) caused 57% of admissions, and infective illness 44%. FTT, failure to thrive; URTI, upper respiratory tract infection; UTI, urinary tract infection. Source: Y. Thakker, T.A. Sheldon, R. Long, R. MacFaul (1994). Archives of Disease in Childhood 70: 488–92.
Changes in hospital care

• The average stay in hospital is much shorter.
• There are similar numbers of medical and surgical admissions.
• More children are admitted – 1 in 4 by age 2 years, 1 in 3 by 4.5 years.
• Many medical and surgical procedures are done as day cases.
• Parents are actively involved in care.
• Outreach nursing teams and day assessment units reduce the need for admission.
• Neonatal care makes increasingly heavy demands on resources.

A young child separated from his mother may go through three stages:

Protest: he cries for her return.
Withdrawal: he curls up with a comfort blanket or toy and loses interest in food and play.
Denial: he appears happy, making indiscriminate friendships with everybody. This can be mistakenly interpreted as the child having ‘settled,’ but the mother–child bond has been damaged and will have to be rebuilt. On returning home, he may exhibit tantrums, refuse food or wet his bed.

These problems can be avoided or minimized by:

• Avoiding hospital admission if possible
• Reducing the length of any admission to the minimum
• Performing operations (e.g. herniotomy, orchiopexy) and investigations (e.g. jejunal biopsy, colonoscopy) as day cases
• Encouraging parents to visit often and arranging for one to sleep alongside a young child.

Hospital organization can also help to reduce stress. Paediatric wards mean that children are looked after by staff specially trained and experienced in the care of children in a child-friendly environment. Teachers, nursery nurses and play leaders organize education and play. The first impression of a children’s ward should be of happy chaos, rather than of the highly technical medicine, which is in fact going on.

Summary

Although most of this book will focus on illness and disease in children, the issues we have covered in this chapter are vital to understanding child health, and need to underpin all your work with children and families. Most of the global burden of childhood disease is in developing countries, and the good news is that progress is being made to reduce this. Health inequalities are important to UK child health – if poverty could be eradicated, more than 1000 child deaths each year would be prevented. Health promotion is of great importance, as are the social aspects of child health. When you meet children and their families in hospital, a thoughtful, sensitive and child-friendly approach can transform a ‘job to be done’ into a positive and even therapeutic encounter.

FOR YOUR LOG

• Find out about child health statistics for your local area – in the UK go to www.chimat.org.uk and explore the child health profiles and data atlas.
• Discuss local child health issues with paediatric (and if accessible) public health staff.
• Look up parent support group websites for some of the conditions you come across – Contact a family is a good place to start (www.cafamily.org.uk).
• Visit a pre-school or school catering for children with special health or learning needs if this can be organized within your course.
• Visit community health facilities and primary care – focusing on provision for children.
